

Title	Native Vegetation (Single Attribute) - Moggumbill 7928 VIS_ID 2218
Alternative title(s)	Moggumbill_NVMP_VISmap_2218
Abstract	The Native Vegetation (Single Attribute) - Moggumbill 7928 dataset is a digital spatial layer which identifies areas of native vegetation for the Moggumbill 7928 1:100 000 scale map sheet. The dataset is derived from the Native Vegetation (Multi Attribute) - Moggumbill 7928 dataset, which is based on the interpretation of 1:50 000 scale colour aerial photography and supplemented by geo-rectified Landsat TM false colour satellite imagery. The dataset was used to produce a final native vegetation map which describes the distribution and extent of extant native vegetation communities. The map is accompanied by a detailed report. The dataset is part of a series of Native Vegetation (Single Attribute) and Native Vegetation (Multi Attribute) datasets captured as a set of 1:100 000 map sheet tiles by the Native Vegetation Mapping Program (NVMP). (VIS_ID 2218; ANZNS0359100127)

Lineage	Native vegetation information was collected in textual format as survey site data during a botanical survey. Trained botanists visited a series of survey sites (quadrats) and collected plant species data. The location of these quadrats was based on random sampling of Environmental Stratification Units (ESU) generated through stratifying the study area using existing digital spatial layers. Once the survey was completed then botanical records were evaluated using PATN analysis to generate floristic groups. Simultaneously, spatial information was captured through the interpretation of 1:50 000 scale colour aerial photography supplemented by geo-rectified Landsat TM false colour satellite imagery. The aerial photography was dated 12/12/96, 24/12/97 and 25/12/97 and the date of the imagery was 27/04/00. Pairs of aerial photographs were viewed in stereo using a stereoscope. This process revealed a series of patterns which reflected soil, landform and vegetation types. Satellite imagery was viewed to aid in pattern identification. In general, patterns were delineated as polygons for the stereo overlap area of each air photo. Polygons were drawn onto individual transparent acetate overlays. The minimum polygon size was 25ha. However, when possible, communities of significance less than 25ha were delineated. In general, linework from each overlay was then transferred to 1:50 000 transparent mylars, which were referenced to a geo-rectified satellite image to minimise distortion. The final line work was captured digitally through scanning each mylar and was edited and built as a polygon coverage using Genamap GIS software. Nine attributes were captured for each polygon and a digital spatial layer was generated (Native Vegetation (Multi Attribute) - Moggumbill 7928). The accuracy of these attributes was checked with limited fieldwork and corrected if necessary. These attributes were then merged with floristic group data to assist with the assignment of a final vegetation community code, which became a tenth attribute. The Native Vegetation (Single Attribute) - Moggumbill 7928 spatial layer was then derived and used to produce a final native vegetation map.
