Title	Southeast and Tablelands Regional Plan Corridors
Abstract	Biodiversity corridors which are identified for consideration in the South East and Tablelands Regional Plan. These corridors were mapped by refining connectivity models for a range of fauna species, through a process of on ground validation and local knowledge. Local experts who contributed to the final map include staff from all local governments within the planning region, LLS, and National Parks staff.

ArcGIS REST	Name: ArcGIS REST Service
Service	Protocol: WWW:DOWNLOAD-1.0-httpdownload
	Description:
	An ArcGIS Server web service represents a GIS resource such as a map, locator, or image that is located on an ArcGIS Server site and is made available to client applications. Depending on the layers enabled, this web service allows a user to query its features and/or visualise the dataset. This service is aimed at advanced geographical information users, and will require access to geographical information system (GIS) software such as ArcGIS/ArcMap.

Lineage	 Corridor mapping for the Far South Coast (OEH 2013). This mapping was done by taking the "Least Cost Path" analysis (NPWS 2001, Pennay unpublished, Turner unpublished) and refining it to state and regional scale and validating it to known areas of native vegetation that was not already zoned for further development under standard instrument LEPs
	 standard instrument LEPs Southern Rivers NRM Stream 1 Habitat and Connectivity Modelling (SELLS 2015). This mapped habitat and connectivity modelling by systematically identifying those parts of the landscape that provide the resources necessary to support viable species populations, and connected areas that facilitate species movement for the purpose of foraging, interaction and dispersal. Each locations connectivity value is dependent on its condition, locality and how well connected it is to areas providing habitat resources. Connectivity modelling was performed for groups of species using the LINKS (Drielsma, Manion, Ferrier 2007) least cost paths analysis technique. The groups of species were. This approach considers the accessibility and permeability of each location in the landscape from a species perspective along with information on the average distance species are likely to disperse. The models used for this project were for the following groups of species: a. Wet and Dry Forest Species (limited dispersal) b. Wet and Dry Forest Species (intermediate dispersal) c. Woodland and Dry Forest Species (limited dispersal) e. Open Woodland Species (limited dispersal) f. Open Woodland Species (intermediate dispersal) f. Open Woodland Species (intermediate dispersal) f.

6. The NVMBM has used the Biodiversity Forecaster Tool to predict where the greatest benefit to biodiversity at the State scale is predicted to be achieved from management of native vegetation. This mapping has identified connectivity areas across the state that have been classified as either consolidate, manage, improve or revegetate. These management classifications have been validated and also added to the final corridors mapping produced for this report. All vegetation mapping data held corporately within the OEH database was collated, with additional mapping products from local government and development applications also sourced.
